

For the assessment, we were given CSV files, and since they were large in size, I first extracted them to my folder. We were also given a GeoJSON file. I did not know what to do with it, and I thought of converting it into a CSV. But I searched what it is first, then knew that I did not need to convert it because it is a visualization. In my data preparation, I first tried to use Python, but I had a hard time since I was using Colab and the RAM usage when running the cells exceeded the RAM limit of Colab. With this difficulty, I then switched the runtime to R. It was easier, and Colab was able to handle it easily. I cleaned the CSV files and merged them into a single file. There were inaccuracies in the visualizations on Tableau, but the error was in the merged file, so I just edited the code and downloaded the merged file again.

I used the type of charts depending on what is needed on the dashboard. I just used the standard colors and did not change them anymore, as it is readable already on my part. Keeping it plain would be enough for me as long as I can interact with it.

Looking at the visualizations presented using Tableau, I noticed that the data points have very small differences from each other. Some of the differences are only by decimals, which makes it look like a straight line when the axis starts from zero. In line with this, I unchecked the box that makes it start from zero, which revealed a zigzag line.

I structured my dashboard depending on what they visualize. The trends and calculations, as it would be seen as simple, where they can see the basic information that can prove useful or a simple analysis. The Analysis dashboards would be at the latter part of the narrative because it would be deeper than the first part, and it is like an explanation of the first few dashboards. The availability would be the last because it would be just extra information.
